

Optimal Deposit Insurance: Direct Measurement

Eduardo Davila & Itay Goldstein

October 2022

Import Data

WRDS CDS data. Quotes restricted to be: North America, United States, USD, senior and financials.

We filter the following banks: C BACF-BankNA BACORP JPM WB WFC BK STT GS MWD MER

Firm	Ticker
Bank of America NA	BACF-BankNA
Bank of America Corp	BACORP
Bank of NY Mellon	BK
Citigroup Inc	C
Goldman Sachs	GS
JP Morgan Chase	JPM
Merrill Lynch & Co Inc	MER
Morgan Stanley	MWD
State Street Corp	STT
U.S. Bancorp	USB
Wachovia Corp	WB
Wells Fargo & Co	WFC

We then create implied default probabilities. `banks <- c("C", "BACF-BankNA", "BACORP", "JPM", "WB", "USB", "WFC", "BK", "STT", "GS", "MWD", "MER")`

We only keep BoA Corp, which is the whole corporation. BoA NA has poor quality quotes too. We also drop U.S. Bancorp for the same reason.

We also import data from FDIC failure statistics.

```
cds <- read.dta("data_raw/wrds_markit_long.dta") %>%
  select(date, ticker, shortname, rating5y, spread5y, recovery) %>%
  mutate(implicit_def_prob = spread5y/(1 - recovery))

cds <- cds %>% filter(!ticker %in% c("BACF-BankNA", "USB"))

# FDIC

failures <- read.csv("data_raw/failures_by_year.csv", header = TRUE) %>%
  select(Year, Total.Institutions.) %>%
  rename(year = Year, failures = Total.Institutions.) %>%
  filter(year != "Total") %>% mutate(year = as.numeric(year), failures = as.numeric(failures))

total <- read.csv("data_raw/summary_by_year.csv", header = TRUE) %>%
```

```

select(YEAR, BANKS) %>%
  rename(year = YEAR, banks = BANKS) %>%
  mutate(year = as.numeric(year), banks = as.numeric(banks))

fdic <- left_join(total, failures, by = "year")

# The maximum and minimum dates are

first_date <- min(cds$date)
last_date <- max(cds$date)

```

The first date in the dataset is 2004-01-01.

The last date in the dataset is 2014-09-19.

FDIC data

```

fdic <- fdic %>% mutate(failure_rate = failures/banks)

avg_failure_rate <- fdic %>% summarize(mean(failure_rate))
avg_failure_rate_pre08 <- fdic %>% filter(year <= 2007) %>% summarize(mean(failure_rate))

```

The average implied probability of failure is 0.426370374183985%.

The average implied probability of failure is 0.369834999961846% (using data from < 2017).

Range of dates around 08 episode, before, and after

We focus on 2008-10-03.

```

# Number of days
range <- 14

# Dataset filtered around event
df_08 <- cds %>% filter(date >= as.Date("2008-10-03") - range & date <= as.Date("2008-10-03") + range)
before_07 <- cds %>% filter(date <= "2007-01-01")
early_08 <- cds %>% filter(date >= "2008-01-01" & date <= "2008-07-01")
after_09 <- cds %>% filter(date >= "2012-01-01" & date <= "2014-01-01")

# Before, after and whole
mean_before <- mean(before_07$spread5y, na.rm = TRUE)
mean_after <- mean(after_09$spread5y)
mean_full <- mean(cds$spread5y, na.rm = TRUE)
mean_early08 <- mean(early_08$spread5y, na.rm = TRUE)

```

The average implied default rate before 2007 is 0.2268418%.

The average implied default rate after 2009 is 1.5821193%.

The average implied default rate early 2008 is 1.3153546%.

The average implied default rate full is 1.0964889%.

Calculations for 2008 episode

```

change_08 <- cds %>%
  filter(date >= as.Date("2008-10-02") & date <= as.Date("2008-10-03")) %>%

```

```

group_by(ticker) %>%
  summarise(dif      = last(implied_def_prob) - first(implied_def_prob),
            before   = first(implied_def_prob),
            after    = last(implied_def_prob),
            ratio    = last(implied_def_prob)/first(implied_def_prob) - 1)

#change <- cds %>% filter(date >= as.Date("2008-09-29") & date <= as.Date("2008-10-03"))

# Averages before, after, difference, ratio
avg_ratio      <- mean(change_08$ratio)
avg_ratio_neg  <- mean(change_08$ratio[change_08$ratio < 0])
avg_difference <- mean(change_08$dif)
avg_difference_neg <- mean(change_08$dif[change_08$dif < 0])
avg_before     <- mean(change_08$before)
avg_after      <- mean(change_08$after)

ratio_of_averages <- mean(change_08$dif)/mean(change_08$before)

# Large change afterwards
change_08_next <- cds %>%
  filter(date >= as.Date("2008-10-13") & date <= as.Date("2008-10-14")) %>%
  group_by(ticker) %>%
  summarise(dif      = last(implied_def_prob) - first(implied_def_prob),
            before   = first(implied_def_prob),
            after    = last(implied_def_prob),
            ratio    = last(implied_def_prob)/first(implied_def_prob) - 1)

# Averages before, after, difference, ratio
avg_ratio_next      <- mean(change_08_next$ratio)
avg_ratio_neg_next  <- mean(change_08_next$ratio[change_08_next$ratio < 0])
avg_difference_next <- mean(change_08_next$dif)
avg_difference_neg_next <- mean(change_08_next$dif[change_08_next$dif < 0])
avg_before_next     <- mean(change_08_next$before)
avg_after_next      <- mean(change_08_next$after)

ratio_of_averages_next <- mean(change_08_next$dif)/mean(change_08_next$before)

```

The average implied probability on October 2nd is 6.6866212%.

The average implied probability on October 3rd is 6.1132333%.

The average difference in implied probabilities is -0.5733879%.

The average difference in implied probabilities among banks with dif<0 is -1.0574915%.

The average percent decrease in implied probabilities is -5.8351465%.

The average percent decrease in implied probabilities among banks with dif<0 is -12.8727903%.

The difference in the ratio of averages before and after is -8.5751515%.
